

Height difference of air inlet and outlet shaft in generator room

How to measure genset room temperature?

Measure the temperature inside the genset room. Genset room temperature should be measured near air cleaner inlet of engine. Sometimes to ensure proper ventilation, it may be necessary to measure actual airflow by anemometer. Suitable deration is required in case of ducting of alternator air inlet and outlet.

How should a generator be ventilated?

Preferably, the source of ventilation air should be as low as possible and the air should flow over the entire generator set, thereby cooling the alternator, engine block, and radiator (for sets with unit-mounted radiators) to remove the after-cooler and jacket-water heat.

How do I determine genset room airflow requirements?

Use the following method to determine the genset room airflow requirements. The engine and alternator will emit heat to the genset room. In Figure 6-43, this heat is labeled QGS. Consult the Generator Set Data Sheet to determine the amount of heat, as shown in Figure 6-44.

What are the design parameters of a generator?

Generator-room temperature, ventilation airflow, ventilation air cleanliness, and air movement are critical design parameters that must be analyzed during the design process to ensure optimal and reliable operation of the generator set. It is critical that an adequate amount of ventilation airflow be delivered to the generator room.

How much space should a generator have?

I would suggest that you have a clear 6 feet space all the way around each of the generators. That way you would have heat exchange and fresh air flow from the vents. Plus the 6 ft would give maintenance enough room to work or a forklift to pick up to remove. Where you mount the disconnects will make a difference too.

What temperature should a generator exhaust be recirculated?

Under fully loaded conditions, the temperature of flue exhaust from generator sets can be in excess of 900 F and the radiator (engine-driven or remote) discharge air temperature can be in excess of 160 F. Any recirculation of these high-temperature airstreams can cause the ventilation air temperature to exceed the ambient temperature.
